ANTHRAX WARNING!

IF YOU USE HEROIN YOU COULD BE AT RISK

Information for heroin users

This leaflet contains graphic medical images!
BACKGROUND:

On the 17th June 2012, a heroin injector presented to a Berlin Hospital with symptoms of cutaneous anthrax i.e. infection at the injection site. Symptoms were black eschar (black dry scab), massive swelling, erythema (redness) and thrombosis.

Diagnosis was confirmed at the Robert Koch Institute by PCR, and serology showed that this was an anthrax infection due to the injection of an anthrax-contaminated batch of heroin.

Subsequent to the crisis in Scotland during 2009/10, where an outbreak of anthrax infected 47 people, causing 14 fatalities; further cases and deaths were reported in 2012 in Germany, Denmark, and France. Scotland was again affected, with a confirmed case in Lanarkshire on 24th July 2012. INPUD will continue to report on new cases within the European mainland and UK as they emerge.

The spores found in the heroin responsible for the recent cases in Germany were shown to be indistinguishable from those found in the 2009/10 cases in Scotland. This suggests that the same batch of heroin could be responsible.

Research published subsequent to the 2009/10 outbreak has produced no evidence of nefarious intent, with the heroin possibly being contaminated during transit, or from the Afghan source.⁽¹⁾

Given that the global regime of drug prohibition ensures that there is no quality control of street heroin, the identification and removal of contaminated heroin from circulation is impossible, and as such, the recurrence of such outbreaks seems almost inevitable.
Given this fact, batches of contaminated heroin will inevitably recur on the market, causing further needless illness and death. These outbreaks will occur in the future without warning, due to the fact that contaminated heroin has no readily identifiable traits or characteristics – it cooks, runs, tastes and looks like unadulterated heroin.

We want to provide this basic information not only to injecting and smoking heroin users, but also to professionals who may be in contact with them, and people who are able to talk with the drug using communities.

Who contracted anthrax in the 2009-10 outbreak?

All confirmed cases had a history of recent heroin use. Some had deliberately injected into veins or muscle - or accidentally injected into muscle or the fatty tissue just beneath the skin. Some reported only smoking heroin. Some were homeless, others were in settled accommodation. Some – not all – were on methadone treatment.

Ages ranged from late 20s to mid-50s. More men were affected than women, but this does not mean men are more susceptible to anthrax than women, or that women are safer.

Confirmed new cases in 2012-2013:
Source: The Health Protection Agency (HPA):

- 8th March 2013 – “The Health Protection Agency (HPA) is aware that a person who injected heroin has been diagnosed with anthrax infection in Suffolk and has died.”

- 18th December 2012 – “The Health Protection Agency (HPA) is aware that a person who injected heroin has been diagnosed with anthrax infection in Kent. The patient has died. This case
has occurred after two people who injected drugs died from confirmed anthrax infection in Blackpool within a month of each other in August and September of this year.” (2012)

• 2 November 2012 - “The Health Protection Agency (HPA) is aware that a person who injected heroin has been diagnosed with anthrax infection in Oxford. The patient is recovering. This case has occurred after two people who injected drugs died from confirmed anthrax infection in Blackpool within a month of each other in August and September of this year.” (2012)

There is an ongoing outbreak of anthrax among people who inject drugs in a number of countries in Europe, with 14 cases now having been identified since early June 2012. The latest case in Suffolk brings the total number affected in the UK to seven – five in England (including three fatalities), one in Scotland and one in Wales. The source of the infection is presumed to be contaminated heroin.

It is unclear as yet whether these recent cases are linked to the cases in Europe (four in Germany, two in Denmark and one in France) but the HPA is continuing to monitor the situation.

The European Centre for Disease Prevention and Control (ECDC) and the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) have concluded that “heroin users in Europe are still at risk of exposure to anthrax.” (Extract from HPA press release). There appear to be no further cases reported elsewhere in Europe at this time.

These outbreaks will occur in the future without warning, due to the fact that contaminated heroin has no readily identifiable traits or characteristics – it cooks, runs, tastes and looks like unadulterated heroin.
WHAT IS ANTHRAX?

Anthrax is a bacterium, which creates spores that can infect the body, producing lethal poisons and causing death.

Anthrax releases three factors: lethal factor (LF), edema factor (EF) and protective antigen (PA). PA and LF form a lethal toxin, which kills macrophages and inhibits B-cell and T-cell function so minimising the immune response to anthrax.

Anthrax spores are highly resistant to adverse conditions. It will survive boiling, organic solvents such as ethanol, and high variations of pH.

Anthrax infection among heroin users is most likely to be acquired through:

**Injection** - Spores entering the bloodstream, skin or tissues under the skin (such as fat or muscle) via injection of contaminated heroin.

**Inhalation** - Smoking/chasing/snorting: Breathing in spores while smoking or snorting contaminated heroin.

Routes of infection:

There are three main routes of infection:

- **cutaneous** (e.g. via injecting),
- **inhalation** (e.g. inhaling spores through smoking/sniffing)
- **gastrointestinal** (e.g. swallowing, or smuggling internally)

With inhaled anthrax, it was initially thought that spores infect the alveoli in the lungs, but some recent evidence suggests that the spores infect higher up, in the nasopharynx, and only later infect the lungs.
Smuggling heroin:

Although there is no evidence of infections due to smuggling at this time, we strongly advise that people choosing to smuggle heroin internally by swallowing, or by anal and vaginal insertion, be aware that they may be at risk of infection.

Compounding this will be the understandable reluctance in presenting to A&E for fear of possible legal implications. This could result in severe life threatening conditions through gastrointestinal or related internal infections.

Can you identify the contaminated heroin?

No. The anthrax spores are too small to be seen with the human eye. The mixture in the cooker/spoon or foil will look, smell and taste the same as an uncontaminated mix.

Anthrax contaminated heroin will cook up, and run on foil in exactly the same way that an uncontaminated batch would.

Can you filter out the anthrax spores?

We do not know how many spores would be in one hit, but there is evidence involving animal studies that it doesn't take many spores to kill a sheep. This indicates that even small amounts of the anthrax bacteria can cause infection, illness and death.
The Sterifilt filter (pictured right) is not fine enough to remove anthrax spores.

You could try using a .22-micron wheel filter, but this is not guaranteed to remove the anthrax spores. The small number of spores left will still create illness. For some infections as little as one bacillus will create illness.

If you are using a wheel filter, wet the filter first (with sterile, or boiled and cooled water) this stops a lot of the drug being absorbed by the filter. The risk however is not removed and may not even be reduced.

Boiling the mix as a hit will not kill anthrax. The absolute destruct cycle to kill anthrax is boiling for 30 minutes at 132 degrees C. This is impossible with the volume of liquid used in a hit.

Always use new needles / syringes if at all possible. Create safe space and share nothing!

White vs. Brown heroin:

The only ‘safe’ heroin to use would be pharmaceutical diamorphine from a reputable source in a sealed vial. White ‘street’ heroin can’t be guaranteed in either origin, or purity, so could also potentially be contaminated.
SIGNS AND SYMPTOMS:

Early identification of anthrax can be difficult, especially among heroin users whose general health may be poor anyway.

How someone reacts also depends on whether the spores entered through the bloodstream (via injection or sniffing) or through the lungs (via smoking / chasing / snorting).

So look out for anyone who uses heroin and is feeling poorly – especially if they have a wound, redness or swelling at, or close to, an injecting site.

Other early symptoms can be similar to other illnesses like the flu, or feeling nauseous or even having difficulty breathing.

Someone may be infected with anthrax if he or she shows any of the following:

Anthrax infection at an injecting site (below the skin, in subcutaneous fat or muscle tissue):

• Infection (redness and swelling) of the injection site or an area close to it.
• Tenderness/pain/discharge of fluid or pus from wounds.
• A raised temperature and feeling generally unwell and weak, with aches and pains including headache.

Anthrax infection in the skin (classical cutaneous/skin anthrax):

• Usually occurs 2-12 days after exposure.
• Usually begins as a raised/swollen itchy red bump, similar to an insect bite.
• Within 1-2 days, develops into a clear blister/abscess and then an ulcer that may be painless. It may also be black in the centre.
Anthrax warning! Information for heroin users

Issue 3 – March 2013

- Feeling flu-like with fever, headache and/or nausea.
- Person-to-person spread of cutaneous anthrax is extremely rare.

Anthrax infection though inhaling (inhalation anthrax):

- Flu like illness (fever, headache, muscle aches, cough), which may cause breathlessness and chest pains.
- Rapid deterioration of consciousness – lapsing into a coma. This might be confused for an overdose, but unlike an OD, it will not be reversed by naloxone.

Advanced infections:

INPUD has received permission to use clinical images of advanced anthrax infection (page 11). This is with view to encouraging heroin users, who believe they may have been exposed to anthrax, to seek urgent medical attention.

Please be aware that these are not images of early presentation, but medical images of advanced infection when early treatment with antimicrobials and other adjuvant therapies are not accessed.

What to do if someone has symptoms:

If a heroin user shows any of the described symptoms, you should **actively assist** them to be seen urgently by their nearest hospital accident and emergency department or GP.

**Things you can do include:**
- Helping them find their way to hospital or GP surgery.
- Accompanying them to hospital or surgery.
- Arranging for someone else – family or friend – to be there with them.

Early Identification:

The timescale of 1-12 days for symptoms to present may depend on the frequency of heroin use, the route of administration and the current health of the individuals using heroin. If they’re in poor health to begin with, the clinical presentations may vary, as will the timescales for symptoms to present.

**TREATMENT:**

Early diagnosis and treatment with potent antibiotics are essential in any of the three clinical forms of anthrax: cutaneous, gastrointestinal and pulmonary. Unfortunately, the bacteria have evolved resistance to common antibiotics including ciprofloxacin, doxycycline and beta-lactam type drugs.

*The 2001 US outbreak, the 2009/10 outbreak in Scotland, and the more recent European and UK experience with people who inject drugs, have once again shown that this infection, while rare in developed areas, is still a significant risk to our community.*
Are there risks to family, friends or medical staff?

- The risk to non-heroin using individuals appears to be minimal.
- There are no documented cases of infection spreading from one person to another as a result of any form of intimate physical or sexual contact.
- There is a potential risk from touching skin lesions, especially where skin is broken.
- Healthcare advice should be taken on the best way to heal a wound.
- Small wounds can be covered with a waterproof dressing.
- Wounds should be dressed and not leak through the dressing.
- Care should be taken to avoid contact with the wound or any wound discharge by wearing single use gloves to dress wounds or to clean up any spillages.
- Afterwards, remove gloves and wash hands with soap and water.

Person to person contact:

There is no data suggesting that patient-to-patient or person-to-person transmission of anthrax occurs. Therefore, while standard barrier precautions are recommended for all hospitalized anthrax patients, the use of airborne protection measures is not indicated.

Contact isolation precautions should be used for patients when draining cutaneous anthrax lesions. Healthcare workers or household contacts should only receive post-exposure prophylaxis if it is determined that those persons were exposed to anthrax aerosol or surface contamination.
